# Static Program Analysis Part 7 – interprocedural analysis

http://cs.au.dk/~amoeller/spa/

Anders Møller & Michael I. Schwartzbach Computer Science, Aarhus University

#### Interprocedural analysis

- Analyzing the body of a single function:
  - intraprocedural analysis
- Analyzing the whole program with function calls:
  - interprocedural analysis
- For now, we consider TIP without function pointers and indirect calls
- A naive approach:
  - analyze each function in isolation
  - be maximally pessimistic about results of function calls
  - rarely sufficient precision...

#### **CFG** for whole programs

#### The idea:

- construct a CFG for each function
- then glue them together to reflect function calls and returns

#### We need to take care of:

- parameter passing
- return values
- values of local variables across calls (including recursive functions, so not enough to assume unique variable names)

### A simplifying assumption

Assume that all function calls are of the form

$$X = f(E_1, ..., E_n);$$

This can always be obtained by normalization

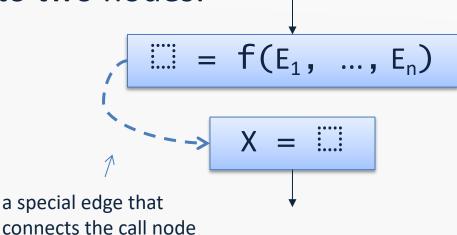

## Interprocedural CFGs (1/3)

#### Split each original call node

$$X = f(E_1, ..., E_n)$$

#### into two nodes:

with its after-call node

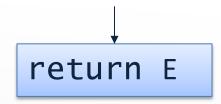

the "call node"

\_\_\_ the "after-call node"

## Interprocedural CFGs (2/3)

Change each return node

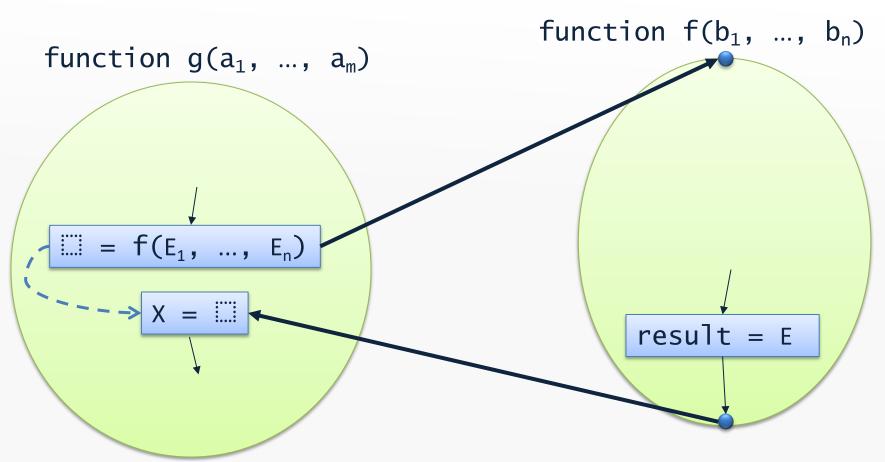

into an assignment:

(where result is a fresh variable)

## Interprocedural CFGs (3/3)

Add call edges and return edges:

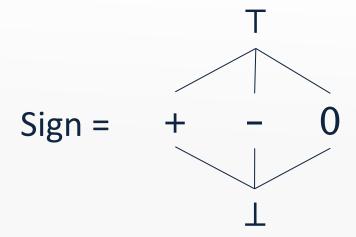

#### **Constraints**

- For call/entry nodes:
  - be careful to model evaluation of all the actual parameters before binding them to the formal parameter names (otherwise, it may fail for recursive functions)

- For after-call/exit nodes:
  - like an assignment: X = result
  - but also restore local variables from before the call using the call after-call edge
- The details depend on the specific analysis...

#### **Example: interprocedural sign analysis**

- Recall the intraprocedural sign analysis...
- Lattice for abstract values:

Lattice for abstract states:

$$Vars \rightarrow Sign$$

## **Example: interprocedural sign analysis**

• Constraint for entry node v of function  $f(b_1, ..., b_n)$ :

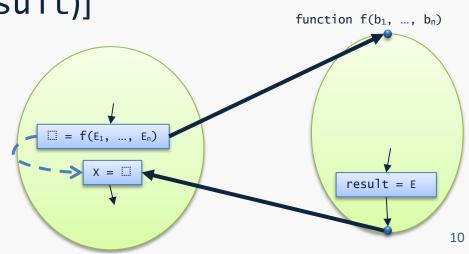

$$\llbracket v \rrbracket = \coprod \coprod [b_1 \rightarrow eval(\llbracket w \rrbracket, E_1^w), ..., b_n \rightarrow eval(\llbracket w \rrbracket, E_n^w)]$$

$$w \in pred(v)$$
where  $E_i^w$  is i'th argument at w

Constraint for after-call node v labeled X = ::::,
 with call node v':

 $[v] = [v'][X \rightarrow [w](result)]$ where  $w \in pred(v)$ 

(Recall: no global variables, no heap, and no higher-order functions)

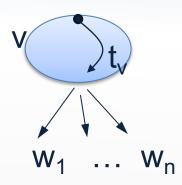

# The worklist algorithm (original version)

```
X_1 = \bot; ... X_n = \bot
W = \{V_1, \ldots, V_n\}
while (W \neq \emptyset) {
  V_i = W.removeNext()
  y = f_i(x_1, \ldots, x_n)
  if (y \neq x_i) {
     for (v_i \in dep(v_i)) {
        W.add(v_i)
     x_i = y
```

# The worklist algorithm (alternative version)

```
X_1 = \bot; ... X_n = \bot
W = \{v_1, \dots, v_n\}
while (W \neq \emptyset) {
  V_i = W.removeNext()
  y = t_i(x_i)
  for (v_i \in dep(v_i)) {
     propagate(y, v_i)
```

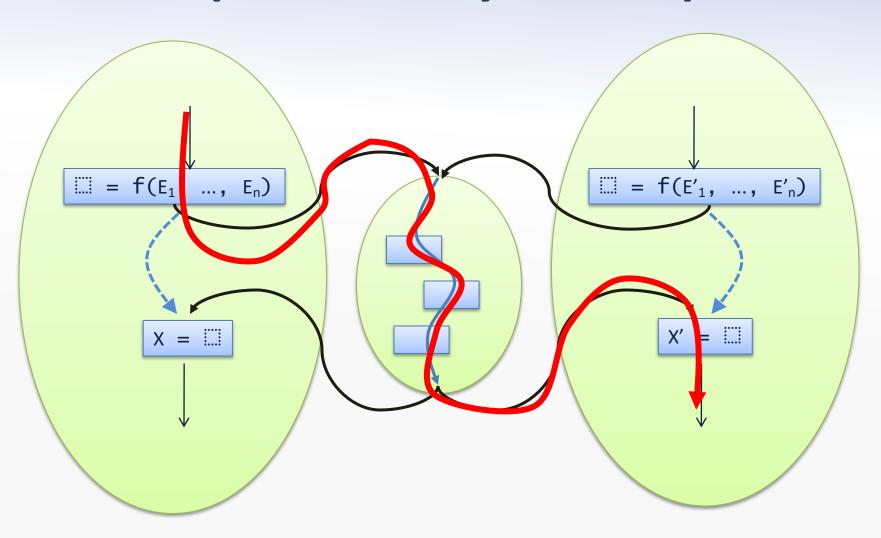

```
propagate(y, v_j) {
Z = X_j \sqcup y
if (z \neq X_j) \{
X_j = Z
W. add(v_i)
```

Implementation: WorklistFixpointPropagationSolver

### Agenda

- Interprocedural analysis
- Context-sensitive interprocedural analysis

## Interprocedurally invalid paths

#### Example

What is the sign of the return value of g?

```
f(z) {
  return z*42;
g() {
  var x,y;
  x = f(0);
  y = f(87);
  return x + y;
```

Our current analysis says "T"

# Function cloning (alternatively, function inlining)

- Clone functions such that each function has only one callee
- Can avoid interprocedurally invalid paths ©
- For high nesting depths, gives exponential blow-up
- Doesn't work on (mutually) recursive functions

 Use heuristics to determine when to apply (trade-off between CFG size and precision)

#### Example, with cloning

What is the sign of the return value of g?

```
f1(z1) {
  return z1*42;
f2(z2) {
  return z2*42;
g() {
 var x,y;
  x = f1(0);
  y = f2(87);
  return x + y;
```

### Context sensitive analysis

- Function cloning provides a kind of context sensitivity (also called polyvariant analysis)
- Instead of physically copying the function CFGs, do it *logically*
- Replace the lattice for abstract states, States, by

Contexts → lift(States)

#### where Contexts is a set of call contexts

- the contexts are abstractions of the state at function entry
- Contexts must be finite to ensure finite height of the lattice
- the bottom element of lift(States) represents "unreachable" contexts
- Different strategies for choosing the set Contexts...

#### One-level cloning

- Let c<sub>1</sub>,...,c<sub>n</sub> be the call nodes in the program
- Define Contexts= $\{c_1,...,c_n\} \cup \{\epsilon\}$ 
  - each call node now defines its own "call context" (using  $\epsilon$  to represent the call context at the main function)
  - the context is then like the return address of the top-most stack frame in the call stack
- Same effect as one-level cloning, but without actually copying the function CFGs
- Usually straightforward to generalize the constraints for a context insensitive analysis to this lattice
- (Example: context-sensitive sign analysis later...)

## The call string approach

- Let c<sub>1</sub>,...,c<sub>n</sub> be the call nodes in the program
- Define Contexts as the set of strings over {c<sub>1</sub>,...,c<sub>n</sub>} of length ≤k
  - such a string represents the top-most k call locations on the call stack
  - the empty string  $\epsilon$  again represents the call context at the main function
- For k=1 this amounts to one-level cloning

Implementation: CallStringSignAnalysis

#### **Example:**

#### interprocedural sign analysis with call strings (k=1)

Lattice for abstract states: Contexts  $\rightarrow$  lift(Vars  $\rightarrow$  Sign) where Contexts= $\{\varepsilon, c_1, c_2\}$ 

```
f(z) {
 var t1, t2;
  t1 = z*6;
  t2 = t1*7;
  return t2;
x = f(0); // c1
y = f(87); // c2
```

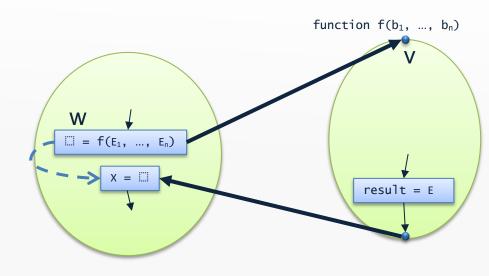

```
\varepsilon \mapsto unreachable,
 c1 \mapsto \bot[z\mapsto 0, t1\mapsto 0, t2\mapsto 0],
 c2 \mapsto \bot[z\mapsto +, t1\mapsto +, t2\mapsto +]
```

What is an example program that requires **k=2** to avoid loss of precision?

## Context sensitivity with call strings function entry nodes, for k=1

Constraint for entry node v of function  $f(b_1, ..., b_n)$ : (if not 'main')

$$[v](c) = \bigcup s_w^{c'}$$
 $w \in pred(v) \land$ 
 $c = w \land$ 
 $c' \in Contexts$ 

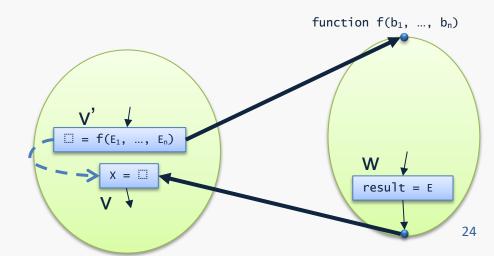

$$s_{w}^{c'} = \begin{cases} unreachable & if [[w]](c') = unreachable \\ \bot[b_{1} \rightarrow eval([[w]](c'), E_{1}^{w}), ..., b_{n} \rightarrow eval([[w]](c'), E_{n}^{w})] & otherwise \end{cases}$$

# Context sensitivity with call strings after-call nodes, for k=1

Constraint for after-call node v labeled  $X = \square$ , with call node v' and exit node  $w \in pred(v)$ :

$$\llbracket v \rrbracket(c) = \begin{cases} unreachable & \text{if } \llbracket v' \rrbracket(c) = unreachable \\ \llbracket v' \rrbracket(c) [X \rightarrow \llbracket w \rrbracket(v') (result)] & \text{otherwise} \end{cases}$$

#### The functional approach

- The call string approach considers control flow
  - but why distinguish between two different call sites if their abstract states are the same?
- The functional approach instead considers data
- In the most general form, choose
   Contexts = States
   (requires States to be finite)
- Each element of the lattice States → lift(States)
   is now a map m that provides an element m(x) from
   States (or "unreachable") for each possible x
   where x describes the state at function entry

#### **Example:**

interprocedural sign analysis with the functional approach

Lattice for abstract states: Contexts  $\rightarrow$  lift(Vars  $\rightarrow$  Sign) where Contexts = Vars  $\rightarrow$  Sign

```
f(z) {
 var t1, t2;
  t1 = z*6;
  t2 = t1*7;
  return t2;
x = f(0);
y = f(87);
```

```
 \begin{bmatrix} \bot[z\mapsto 0] \mapsto \bot[z\mapsto 0, \ t1\mapsto 0, \ t2\mapsto 0], \\ \bot[z\mapsto +] \mapsto \bot[z\mapsto +, \ t1\mapsto +, \ t2\mapsto +], \\ \text{all other contexts} \mapsto \text{unreachable} \end{bmatrix}
```

### The functional approach

- The lattice element for a function exit node is thus a function summary that maps abstract function input to abstract function output
- This can be exploited at call nodes to skip function!
- When entering a function with abstract state x:
  - Consider the function summary s for that function
  - If s(x) already has been computed, use that to model the entire function body, then proceed directly to the after-call node
- Avoids the problem with interprocedurally invalid paths!
- ...but may be expensive if States is large

Implementation: FunctionalSignAnalysis

# Context sensitivity with the functional approach function entry nodes

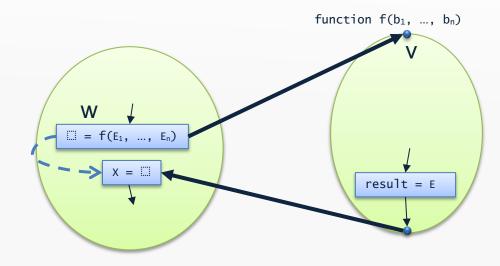

Constraint for entry node v of function  $f(b_1, ..., b_n)$ : (if not 'main')

$$[v](c) = \bigsqcup s_w^{c'}$$

$$w \in pred(v) \land$$

$$c = s_w^{c'} \land$$

$$c' \in Contexts$$

where s<sub>w</sub> is defined as before

# Context sensitivity with the functional approach after-call nodes

Constraint for after-call node v labeled  $X = \square$ , with call node v' and exit node  $w \in pred(v)$ :

$$\llbracket v \rrbracket(c) = \begin{cases} \text{unreachable if } \llbracket v' \rrbracket(c) = \text{unreachable } V \llbracket w \rrbracket(s_{v'}^c) = \text{unreachable } \\ \llbracket v' \rrbracket(c) [X \rightarrow \llbracket w \rrbracket(s_{v'}^c) (\text{result})] \end{cases}$$
 otherwise
